

# Capstone

Automating BDD Scenarios

# Admin

- Project:
  - If I have OKed your group's proposal, write me first scenarios and then BDD tests for your projects (one submission per student this time)
  - JBehave/cucumber-jvm for Java
  - Behave for python
- Again Credit:
  - Most images in this lecture from [BDD in Action](#) by John Smart

# Benefits of Automated Scenarios

- Benefits of automated acceptance testing
  - Testers spend less time of regression testing
  - New versions released faster
  - Automated scenarios give accurate 'vision' of current state of project

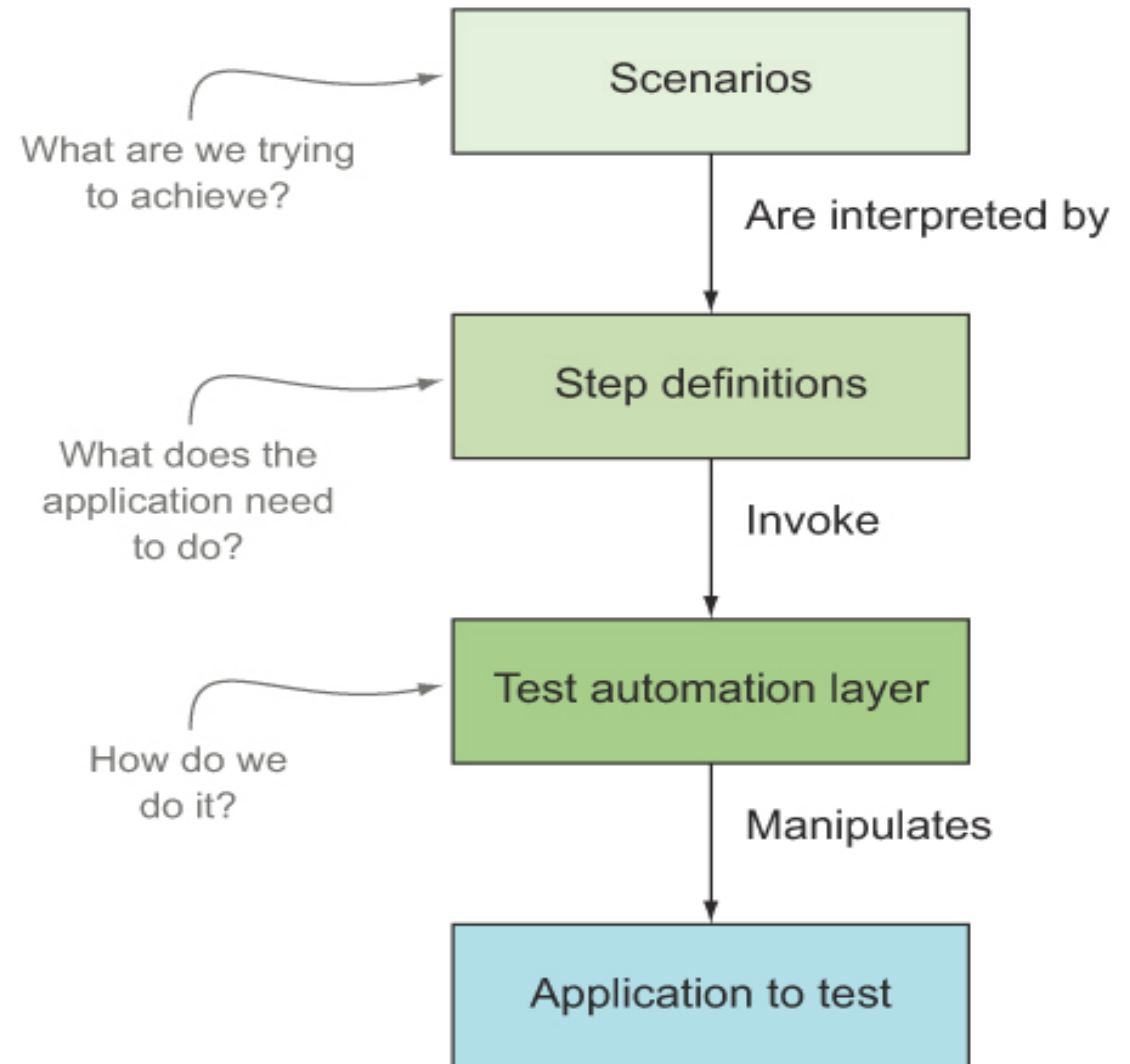

# Continuous Integration and Testing

- <https://www.youtube.com/watch?v=RcTFpNIkiUs>
- For first section

# Layers in Test Automation

- Got Scenarios
- Now step defs

Figure 6.3. A well-designed test automation suite has a number of layers.

# Test Automation Layers Example

- This is how it might look

- *Scenarios* describe the high-level requirement:

```
Scenario: Earning standard points from an Economy flight
Given the flying distance between Sydney and Melbourne is
878 km
And I am a standard Frequent Flyer member
When I fly from Sydney to Melbourne
Then I should earn 439 points
```

- *Step definitions* interpret the scenario texts and call the test automation layer to perform the actual tasks:

```
@Given("the flying distance between $a and $b is $distance
km")
public void defineTheFlyingDistanceForATrip(...) {...}
```

- *The test automation layer* interacts with the application under test:

```
inTheTestDatabase.theDistanceBetween(departure)
    .and(destination)
    .is(distance);
```

# Scenario Outcomes

- Standard tests (TDD unit tests)
  - Two outcomes
  - Which are?

# Scenario Outcomes

- Standard tests (TDD unit tests)
  - Two outcomes
    - Red bar (fail)
    - Green bar(pass)
- BDD Tests
  - Add more
    - Pending (throw new PendingException)
    - Skipped (tests after failed or pending test)
    - work-in-progress

# JBehave Step Definition

- Example step definition

```
FrequentFlyerMember member;

public class EarningPointsSteps {
    @Given("I am a $status Frequent Flyer member")
    public void defineAMemberWithStatus(String status) {
        member = Members.getMember().withStatus(status);
    }
}
```

Step definitions are marked by an annotation.

You'll need to use the member in later steps.

Step definitions can go in any class.

The method name has no importance.

Here you interact with the application, by manipulating the UI or via API calls, to perform the corresponding application logic.

- Or from table

```
SimpleDateFormat formatter = new SimpleDateFormat("dd-MM-yyyy");

@Given("I have travelled on the following flights: $flights")
public void travelled_on_flights(ExamplesTable flights)
    throws ParseException {
    for(Map<String,String> flightDetails : flights.getRows()) {
        Flight flight = Flight.number(flightDetails.get("flight"))
            .from(flightDetails.get("from"))
            .to(flightDetails.get("to"));

        Date date = formatter.parse(flightDetails.get("date"));
        member.flewOnFlight(flight).on(date);
    }
}
```

A date formatter used to parse the date column.

Iterate over the rows in the table.

Pass the table as an ExamplesTable.

Extract field values from the row.

Update the test database with the new data.

# In Python using behave

- Using behave

```
Feature: Transfer points to other members
```

```
@transfers
```

```
Scenario: Transfer points between existing members
```

```
Given the following accounts:
```

owner	points	statusPoints
Jill	100000	800
Joe	50000	50

```
When Joe transfers 40000 points to Jill
```

```
Then the accounts should be the following:
```

owner	points	statusPoints
Jill	140000	800
John	10000	50

Behave will pass the tabular data to each step in the context object, as illustrated here:

```
@given('the following accounts')
def step_impl(context):
    for row in context.table:
        owner = row["owner"]
        points = row["points"]
        statusPoints = row["statusPoints"]
```

← Tabular data is passed in the context.table variable.

Extract values from each row.

# Side note: Tools

- In academia
  - Often testing/learning concepts
  - Often in isolation
  - Long debate:
    - What level of tools should we teach
    - When is it worth the time to invest in tools
- In industry:
  - Going to be working on a project for months not day/weeks
  - Tools always worth learning
  - Startup vs steady state

# Tools often used in java BDD

- Tools for Java BDD

- Often use maven

- <https://maven.apache.org/download.cgi>

- Maven is make for java
      - Make?

- JBehave package

- Simple tutorial
      - <http://jbehave.org/reference/stable/getting-started.html>

- Cucumber:

- Good tutorial
      - <http://www.hascode.com/2014/12/bdd-testing-with-cucumber-java-and-junit/>

# Python and BDD

- Behave library is the goto in python BDD
  - Nice tutorial
    - <http://code.tutsplus.com/tutorials/behavior-driven-development-in-python--net-26547>
  - The official tutorial
- But lettuce is getting popular
  - Java:cucumber as python:lettuce
  - <http://lettuce.it/tutorial/simple.html>
  -
